Project Proposal

The proposed project aims to implement distributed training of a Convolutional Neural Network (CNN) using a pipeline parallelism approach across three machines. Instead of training the entire model on a single machine, the CNN model will be divided into three stages and each stage will be assigned to a separate machine. The first machine will handle the initial convolutional layers, the second machine will process the deeper convolutional layers, and the third machine will handle the flatten operation along with the fully connected layers responsible for classification. This project demonstrates how distributed systems concepts can be applied to machine learning to enable scalable and efficient model training across multiple networked machines.
